

→ Polymorphism :-

Polymorphism is another important OOP concept. Polymorphism, a Greek term, means the ability to take more than one form. An operation may exhibit different behaviours in different instances. The behaviour depends upon the types of data used in the operation.

For example - Consider the operation of addition. For two numbers, the operation will generate a sum.

If the operand are string, then the operation would produce a string by concatenation. The process of making an operator to exhibit different behaviours in different instances is known as operator overloading.

Polymorphism :-
